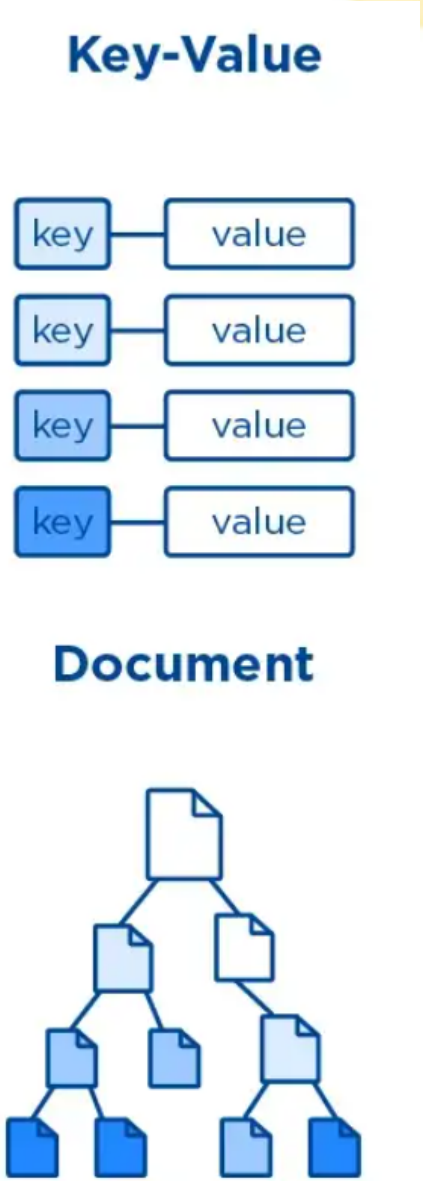
Key-Value Store vs Document DBs

- **Key-value stores**
  - Function as a map or dictionary
    - Examples: HBase, Redis
  - Primarily retrieve values using keys
    - Occasionally search within value fields using patterns
  - Store uninterpreted values (e.g., binary blobs) linked to keys
  - Use a single namespace for all key-value pairs
- **Document DBs**
  - Group key-value pairs into *documents*
    - Examples: MongoDB, CouchDB
  - Documents formatted in JSON, XML, or BSON (binary JSON)
  - Documents are part of *collections*
    - Comparable to *tables* in relational databases
    - Large collections can be partitioned and indexed



MongoDB

- Developed by MongoDB Inc.
  - Founded in 2007
  - Based on DoubleClick experience with large-scale data
  - Mongo comes from "hu-mongo-us"
- Highly popular NoSQL database
- **Document-oriented NoSQL DB**
  - Schema-less
    - No Data Definition Language (DDL) like SQL
    - Store maps with any keys and values
    - Application manages schema, linking documents to meanings
  - Keys are string-stored hashes
    - Each document has a unique `_id` (reserved by Mongo)
  - Values in BSON format
    - Based on JSON (B for Binary)
- Developed in C++
- Supports APIs (drivers) in various languages
  - Examples: JavaScript, Python, Ruby, Java, Scala, C++, etc

MongoDB: Example of Document

- **A document is a JSON data structure**
- It corresponds to a row in a relational DB
  - Without schema
  - Primary key is `_id`
  - Values nested to an arbitrary depth

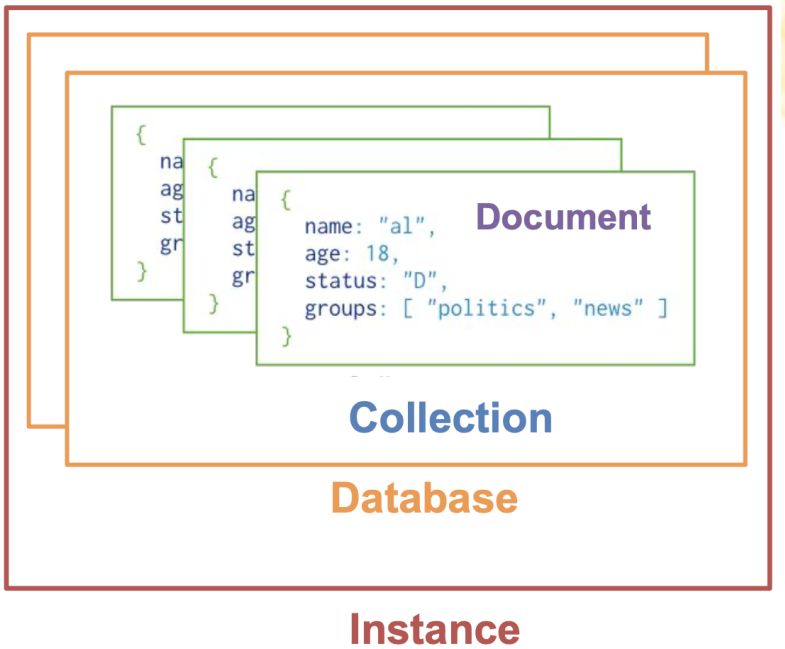
```
{
   "_id" : ObjectId("4d0b6da3bb30773266f39fea"),
   "country" : {
      "$ref" : "countries",
      "$id" : ObjectId("4d0e6074deb8995216a8309e")
   },
   "famous_for" : [
      "beer",
      "food"
   ],
   "last_census" : "Sun Jan 07 2018 00:00:00 GMT -0700 (PDT)",
   "mayor" : {
      "name" : "Ted Wheeler",
      "party" : "D"
   },
   "name" : "Portland",
   "population" : 582000,
   "state" : "OR"
}
```

MongoDB: Functionalities

- **Design goals**
  - Performance
  - Availability/scalability
  - Rich data storage (not rich querying!)
- **Dynamic schema**
  - No DDL
  - Secondary indexes
  - Query language via API
- **Several levels of data consistency**
  - Atomic writes and fully-consistent reads (document level)
- **No joins nor transactions across multiple documents**
  - Distributed queries easy and fast
- **High availability through replica sets**
  - Primary replication with automated failover
- **Built-in sharding**
  - Horizontal scaling via automated range-based partitioning
  - Reads and writes distributed over shards

MongoDB: Hierarchical Objects

- A Mongo **instance** has:
  - Zero or more "databases"
  - Mongo instance ~ Postgres instance
- A Mongo **database** has:
  - Zero or more "collections"
    - Mongo collection ~ Postgres tables
  - Mongo database ~ Postgres database
- A Mongo **collection** has:
  - Zero or more "documents"
    - Mongo document ~ Postgres rows
- A Mongo **document** has:
  - One or more "fields"
    - Always has primary key `_id`
    - Mongo field ~ Postgres columns



Relational DBs vs MongoDB: Concepts

RDBMS Concept	MongoDB Concept	Meaning in MongoDB
database	database	Container for collections
relation / table / view	collection	Group of documents
row / instance	document	Group of fields
column / attribute	field	A name-value pair
index	index	Automatic
primary keys	`_id` field	Always the primary key
foreign key	reference	Pointers
table joins	embedded documents	Nested name-value pairs

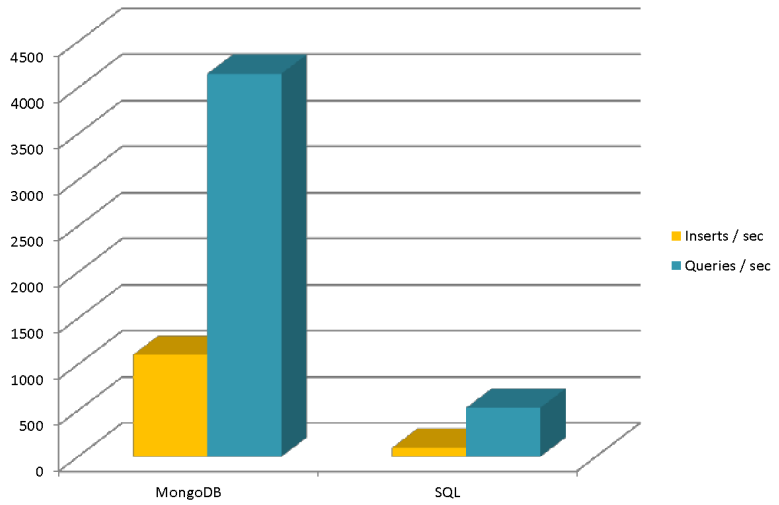
```
{
   "_id" : ObjectId("4d0b6da3bb30773266f39fea"),
   "country" : {
      "$ref" : "countries",
      "$id" : ObjectId("4d0e6074deb8995216a8309e")
   },
   "famous_for" : [
      "beer",
      "food"
   ],
   "last_census" : "Sun Jan 07 2018 00:00:00 GMT -0700 (PDT)",
   "mayor" : {
      "name" : "Ted Wheeler",
      "party" : "D"
   },
   "name" : "Portland",
   "population" : 582000,
   "state" : "OR"
}
```

Relational vs Document DB: Workflows

- **Relational DBs**
  - E.g., PostgreSQL
  - Know what to store
    - Tabular data
  - Static schema allows query flexibility (e.g., joins)
  - Complexity at insertion time
    - Decide data representation (schema)
- **Document DBs**
  - E.g., MongoDB
  - No assumptions on storage
    - E.g., irregular JSON data
  - Access data by key
    - Nested key-value map
  - Complexity at access time
    - Retrieve data from server
    - Process data client-side

Why Use MongoDB?

- Simple to query
  - Work on client side
- Fast
  - 2-10x faster than Postgres
- Data model/functionalities suitable for most web applications
  - Semi-structured data
  - Quickly evolving systems
- Easy and fast data integration
- Not suited for heavy, complex transaction systems
  - E.g., banking system



MongoDB: Data Model

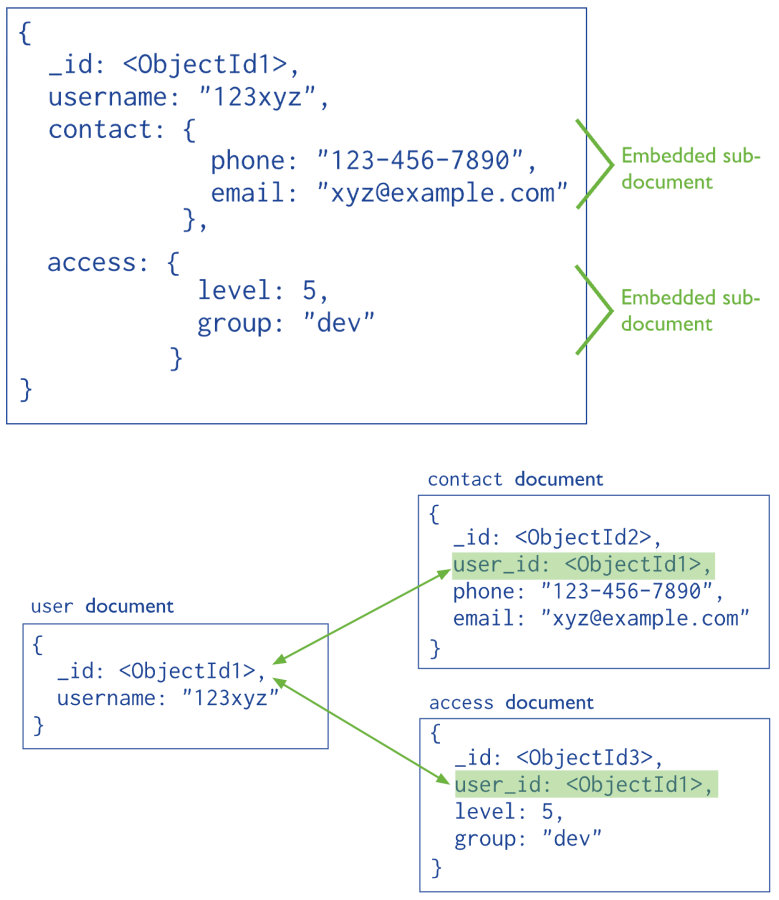
- **Documents** are field-value pairs
  - **Field names**: strings
  - **Values**: any BSON type
    - Arrays of documents
    - Native data types
    - Other documents
- Examples:
  - `_id`: `ObjectId`
  - `name`: document with fields first and last
  - `birth` and `death`: date type
  - `contribs`: array of strings
  - `views`: NumberLong type

```
{
   name: "sue",                          <-- field: value
   age: 26,                              <-- field: value
   status: "A",                          <-- field: value
   groups: [ "news", "sports" ]          <-- field: value
}
```

```
{
   _id: ObjectId("5099803df3f4948bd2f98391"),
   name: { first: "Alan", last: "Turing" },
   birth: new Date('Jun 23, 1912'),
   death: new Date('Jun 07, 1954'),
   contribs: [ "Turing machine", "Turing test", "Turingery" ],
   views : NumberLong(1250000)
}
```

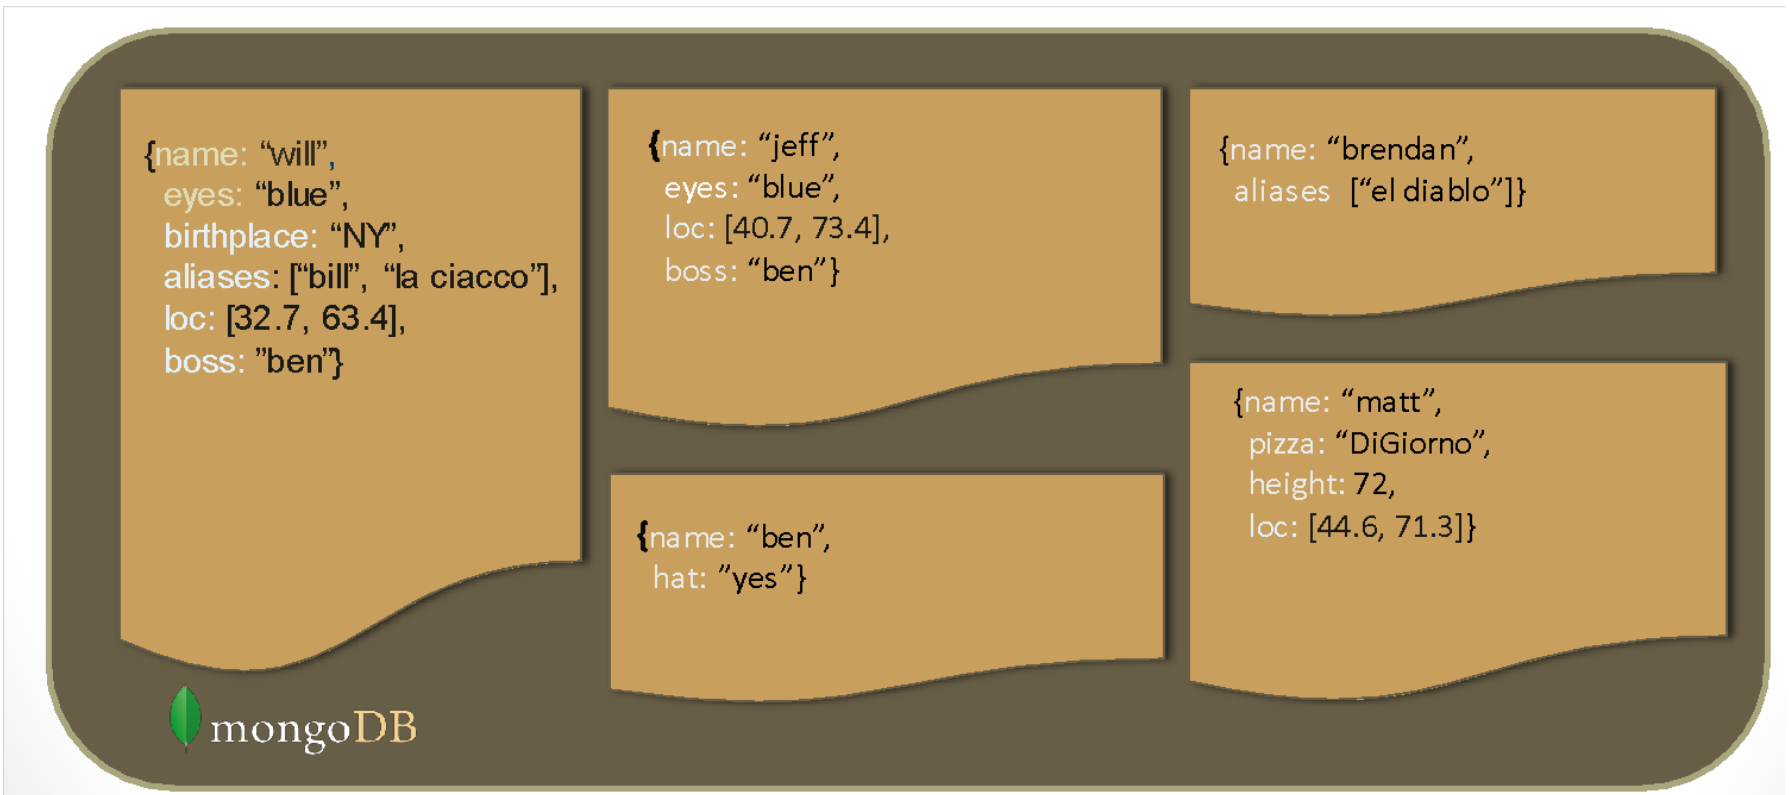
MongoDB: Data Model

- Documents can be nested
  - Embedded sub-document
- **Denormalized data models**
  - Store related information in the same record
  - Result of a join operation
- **Normalized data models**
  - Eliminate duplication
  - Represent many-to-many relationships



Schema Free

- MongoDB does not need pre-defined data schema
- Every **document** in a **collection** can have different fields and values
  - No need for `NULL` values / union of fields like in relational DBs
- E.g., dishomogeneous data instances



JSON Format

- JSON = JavaScript Object Notation
  - Data is stored in field / value pairs
  - A field / value pair consists of:
    - A field name (always a string)
    - Followed by a colon :
    - Followed by a typed value

```
"name": "R2-D2"
```

- **Data in documents is separated by commas ‘,‘**

```
"name": "R2-D2", race: "Droid"
```

- Curly braces {} hold documents

```
{"name": "R2-D2", race : "Droid", affiliation: "rebels"}
```

- An array is stored in brackets []

```
[{"name": "R2-D2", race: "Droid", affiliation: "rebels"},
 {"name": "Yoda", affiliation: "rebels"}]
```

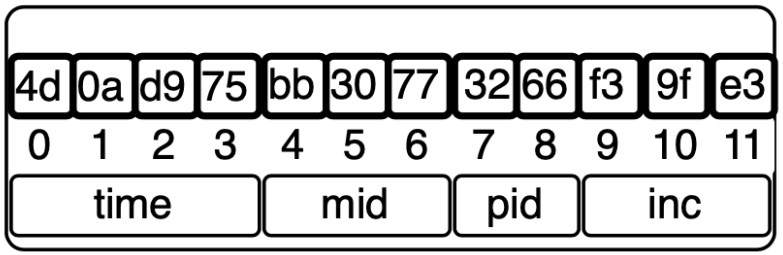
- Supports:
  - Embedding of nested objects within other objects
  - Just references

BSON Format

- Binary-encoded serialization of JSON-like documents
  - https://bsonspec.org
- Store zero or more key/value pairs as a single entity
  - Each entry consists of:
    - Field name (string)
    - Data type
    - Value
- Similar to Protocol Buffer, but more schema-less
- Prefix large elements in BSON document with a length field for scanning
- MongoDB understands BSON objects, even nested
  - Build indexes and match objects against query expressions for BSON keys

ObjectID

- Each JSON data contains an `_id` field of type `ObjectId`
  - Similar to SERIAL constraint incrementing a numeric primary key in PostgreSQL
- An `ObjectId` is 12 bytes, composed of:
  - Timestamp
  - Client machine ID
  - Client process ID
  - 3-byte auto-incremented counter
- Each Mongo process handles its own ID generation without colliding
  - Mongo's distributed nature
- Details here



Indexes

- **Primary index**
  - Automatically created on `_id` field
  - B+ tree indexes
- **Secondary index**
  - Improve query performance
  - Enforce unique values for a field
- Single field index and compound index (like SQL)
  - Order of fields in a compound index matters
- Sparse property of an index
  - Index contains entries for documents with the indexed field
  - Ignore records without the field
- Reject records with duplicate key if index is unique and sparse
- Details here
