 - The Ladder of Causation
 - Correlation vs Causation Models

Big Data and Traditional AI

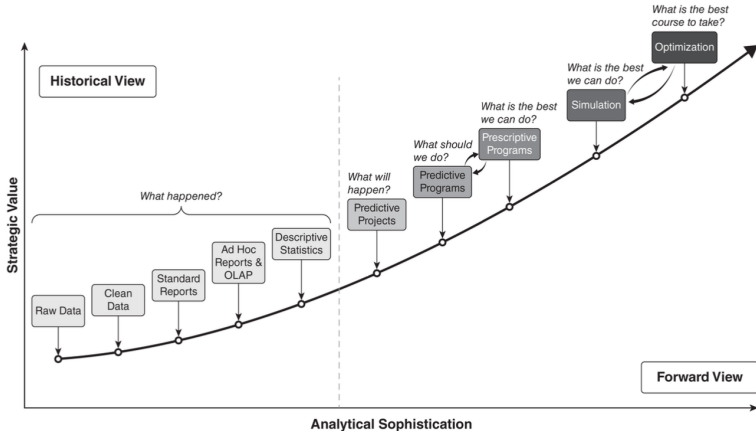

- For the past 10 years, **focus of analytics** on:
 - Organize and analyze massive amount of data
 - Data analytics (dashboards, models, reports)
 - Run machine learning on data
- Problems with **traditional AI**
 - Predicts based on observed correlations
 - Can't explain why an outcome occurred
- **AI in decision making**
 - Understand impact of decisions
 - E.g., *"What happens if a product price is reduced by 10%?"*
 - Will more customers buy?
 - If revenue decreases, what to do?
 - Why are customers leaving? Quality issue? Emerging competitor?

What Are Data Analytics?

- **Collections of data**
 - Aggregated, organized data sets for analysis
 - E.g., customer purchase histories in a CRM system
- **Dashboards**
 - Visual displays of key metrics for insights
 - E.g., dashboard showing quarterly revenue, expenses
- **Descriptive statistics**
 - Summary metrics: mean, median, mode, standard deviation
 - E.g., average sales per quarter to understand trends
- **Historical reports**
 - Examination of past performance
 - E.g., monthly sales reports for past fiscal year
- **Models**
 - Statistical representations to forecast, explain phenomena
 - E.g., predictive model to anticipate customer churn based on behavioral data

Data Analytics Sophistication

| Business Question | Methodology |
|----------------------------|---------------------------|
| What happened? | Descriptive statistics |
| What will happen? | Predictive models |
| What should we do? | Prescriptive programs |
| What's the best we can do? | Simulation + optimization |

Explainability

- **Regulators** require that if you are making decisions using ML / AI, you should be able to defend the results of your analysis
 - E.g., decide who to hire, how to set up a policy
- Organizations can:
 - Be **fin**ed by regulatory authorities
 - Face **backlash** from customers and activists
- E.g., neural networks are “black boxes”
 - Lack of explainability
 - Humans can't understand how inputs are combined into a conclusion
 - Cannot explain to shareholders why certain decisions were made
 - Bias
 - E.g., using age, race, sex as a feature can introduce bias
- **Explainable AI** allow users to:
 - Comprehend
 - Explain
 - Trust the results by the machine

Correlation is Not Causation!

- **Correlation** is a statistical method for understanding relationships between data
 - Pros
 - Use past outcomes to predict future outcomes by finding patterns and anomalies
 - Cons
 - Doesn't explain the cause
 - Variables may move together due to coincidence or a hidden factor
- **Causation** explains how changing one variable influences the other
 - Cannot be concluded from correlation alone
- **Data does not understand causes and effects**
 - Only humans can identify variables and relationships based on context
 - Without causation, you can't make intelligent decisions

Causal AI

- **Understands the why**
 - Determines cause-and-effect between variables
 - E.g., whether a marketing campaign increased sales
- **Identify interventions**
 - Identifies variables and interventions to change outcomes
 - E.g., which lifestyle changes reduce blood pressure
- **Predicting counterfactuals**
 - Hypothesizes outcomes under different circumstances
 - E.g., student grades if they attended a different school
- **Avoiding bias**
 - Traditional AI biased by training data and ignored variables
 - Ensure fairness by accounting for confounding variables
- **Improving decision-making**
 - Provides understanding of relationships for better decisions
 - E.g., improving supply chain by understanding logistic impact

Causal AI vs Traditional AI

- *“The next revolution of data science is the science of interpreting reality, not of summarizing data”* (Judea Pearl, 2021)
- Current AI uses correlation to:
 - Analyze data
 - Identify patterns
 - Make predictions
- Models depend on data quality
 - Biased or unclean data \implies poor model

- Causal AI
 - Why Causal AI?
 - *The Ladder of Causation*
 - Correlation vs Causation Models

The Ladder of Causation

- Pearl provided a 3-layer framework for understanding causality

| Level | Symbol | Activity | Typical Questions |
|--------------------|-------------------|-------------|-------------------|
| 1. Association | $\Pr(Y X)$ | Observing | What is? |
| 2. Intervention | $\Pr(Y do(X), Z)$ | Intervening | What if? |
| 3. Counterfactuals | $\Pr(Y_X x', y')$ | Imagining | Why? |

Rung 1: Association

- **Question:** *“How would seeing X change our belief in Y ?”*
- **Symbol:** $\Pr(Y|X)$
 - Bayesian update
- **Activity**
 - It is just “passive observation”
 - Determine if two things are related
 - Traditional AI and ML is based on this
- **Example**
 - *“The tree has green leaves during spring”*
 - *“What does a symptom tell you about a disease?”*
 - *“What does a survey tell you about the election results?”*

Rung 2: Intervention

- **Question:** *"What happens to Y if you do X ?"*
- **Symbol:** $\Pr(Y|do(X), Z)$
- **Activity**
 - Understand the impact of an action
 - E.g., *"tree has green leaves"* vs *"spring makes tree leaves turn green"*
 - Association is just about observations
 - Interventions involve "doing something" and need a causal model
- **Example**
 - *"Why did the headache go away?"*
 - "Because the pain reliever" or "Because you ate food after skipping lunch"
 - *"If you take aspirin, will your headache be cured?"*
 - *"What if you ban sodas?"*

Rung 3: Counterfactuals

- **Question:** *"Was X that caused Y?"*
- **Symbol:** $\Pr(Y_X|x', y')$
- **Activity:**
 - Imagine what will happen if facts were different
 - Predicting an outcome is the highest form of reasoning
 - It requires to understand relationships between cause and effect
- **Example**
 - Scientific experiments: *"What if we give a child an adult dose of a drug?"*
 - Litigation: *"What would the jury conclude?"*
 - Marketing: *"Why did my marketing campaign fail to generate sales?"*

- Causal AI
 - Why Causal AI?
 - The Ladder of Causation
 - *Correlation vs Causation Models*

Correlation vs Causation Model

- **Correlation** = identify how variables are related to each other
- **Causality** = determine whether one variable causes another variable
 - Both:
 - Accept inputs and transform them to compute predictions
 - Identify how variables are related to each other
 - Correlation-based AI works well when there is abundant historical and observational data
 - Causal-based AI first creates a business-focused model before integrating data

Correlation-Based Model Process

- **Correlation-based AI** is “data first”
 - The more data collected the better
- **Modeling process**
 - Acquire data
 - Integrate and clean data
 - Exploratory data analysis (EDA)
 - Feature engineering
 - Build and test models
 - Deploy models in production
- **Many AI projects fail because**
 - Cultural and organizational issues
 - Models are opaque and lack explainability
 - Spurious correlations
 - Missing articulating “what’s the goal of doing ML?”

Causation-based Model Process

- **Causal AI** is “model first”
 - Understand business question before ingest and transform the data
- **Modeling process**
 - What is the intended outcome?
 - What is the proposed intervention?
 - What are the confounding factors?
 - What are the effecting factors?
 - Create a model graph or diagram
 - Data acquisition
 - ...
